# DESIGN METHODOLOGY FOR A LIGHTWEIGHT, RESONANT-FREE PLATEN FOR VIBRATION TESTING

#### 1. INTRODUCTION

Prudent economics for reliability testing demands that as large a number of test items as possible be placed in an environmental chamber. This permits a rapid accumulation of test hours, thereby gaining high statistical confidence for a given test chamber time. However, serious difficulties can arise when vibration-induced environmental stressing is required. If frequencies are induced that excite the natural frequency of portions of the platen on which the specimens are attached, a resonant condition results. Those test specimens in the resonating area of the platen experience a much higher vibrational stress than either the test plan requires or those items attached to a nonresonating portion of the platen receive. In addition, the location of the resonating portion of the platen changes as different frequency inputs excite different spring-mass systems at their individual natural frequencies.

Naturally, if at a certain frequency, one test specimen is subjected to greater vibration stress than another, the test may provide erroneous failure data for test and reliability analysis. A problem such as this can defeat the entire purpose of the test and cause confusion as to the correct classification of a vibration-caused failure.1

A previous technical report2 discussed two methods of solving or minimizing the resonance problem. One was to design the platen thick enough so that the natural frequency of a loaded corner of a platen would exceed the highest frequency excited by the shaker. If this was impossible because of a weight-displacement limitation of the shaker, then alternatives in the sandwiching of damping materials were offered as an alternate solution. After reanalyzing the contents and causes of platen resonances3 and beam deflection parameters,3 it appears that the design can be refined to get higher natural frequencies at highly significant reductions of weight.

This improvement can take place by removing material from outer portions of the platen, where it is a dead mass, and placing it more in the center, where it adds strength. In reality, the platen takes the form of an inverted, truncated pyramid (ITP) with a square-rectangular-parallelepiped base and top, as illustrated in Figure 1. This report will: (a) present the equations and methods for utilizing this type of design; (b) compare its mass efficiency with that of a constant thickness platen; and (c) discuss the advantages of using magnesium as the platen material. Appendix A contains the derivation of the natural frequency equation used. Appendix B contains a computer program written in Applesoft Basic to ease the burden of repetitive calculations.

#### 2. BENDING MODES OF A RESONATING PLATEN

The Spring-Mass System.

When any structural system vibrates such that the mass for inertial force is identical to the spring (of stiffness) force, the system vibrates at its natural frequency. On a complex structure this can occur at any number of

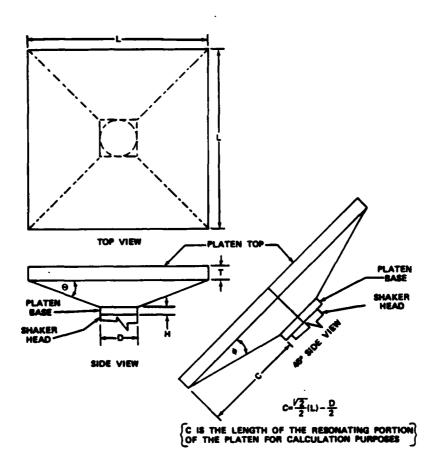

Figure 1. Inverted Truncated Pyramid Type of Platen with Square-Rectangular-Parallelpiped Base and Top and Attached to Cylindrical Shaker Head

Section 1

frequencies when different components combine or separate into different subsystems, each with its own natural frequency. Experience has shown, however, that when a test platen is loaded with many items to be vibrated on a hydraulic or electrodynamic shaker, the corners will go into resonance starting at a line of bending. These lines of bending occur where there is a relatively sudden and significant increase in the platen's area moment of inertia.

#### 3. SUDDEN STIFFNESS CAUSED BY CHANGE IN AREA MOMENT OF INERTIA

Usually test platens are fabricated as a constant thickness slab of a lightweight metal, as illustrated in Figure 2. There is a rapid increase in the section modulus where the platen bolts onto the circular shaker head, caused by both the additional thickness and higher modulus of elasticity. Although the edge of the shaker head is not a true fixed clamp, in that it fixes an entire line of bending in a vise-like grip to form a cantilevered triangular beam, the thickness of the platen forces a straight-line vibration behavior. This has been confirmed by experimental results.2

The ITP type of platen, as shown in Figure 1, will behave the same as the constant thickness platen when it experiences a sudden increase in area moment of inertia. However, two important physical limitations must be taken into account:

- Prudent fabrication techniques require that the base of the platen have a square cross section instead of a round cross section to mate with the shaker head.
- The shaker head is usually about an inch thick. If the slopes of the sides of the inverted pyramid were to be projected to an apex instead of truncated, it would likely project deeper than the thickness of the shaker head.

This indicates that the truncation of the ITP should then have a square base with the same thickness as the removed tip of the pyramid (the precise solid geometric name for this shape would be square-rectangular parallel piped). Also, since the base's square corner does not present a sudden or rapid increase in the area moment of inertia, the line of bending is less precise. Therefore, if the distance "C" from the platen's corner to the line of bending is assumed to be to the shaker-head's circular edge, the most conservative assumption would be used in the calculations. In other words, the actual natural frequency experienced in testing should not exceed that used in any calculations.

### Platen Design Methodology

ALEXANDER AND PROPERTY OF THE PROPERTY OF THE

Appendix A contains the derivation of the equation for determining the natural frequency of a corner of an ITP type of platen. It is Equation A-27 on page 31:

$$f_{N} = 48.47 \sqrt{\frac{E \tan^{3}\phi}{C}} \left( \frac{C\rho \tan\phi + 12 - \frac{W}{A}}{54 C^{2}\rho^{2} \tan^{2}\phi + 1380 C - \rho \tan^{4} + 8960 \frac{W^{2}}{A^{2}}}{A} \right)$$
 (1)

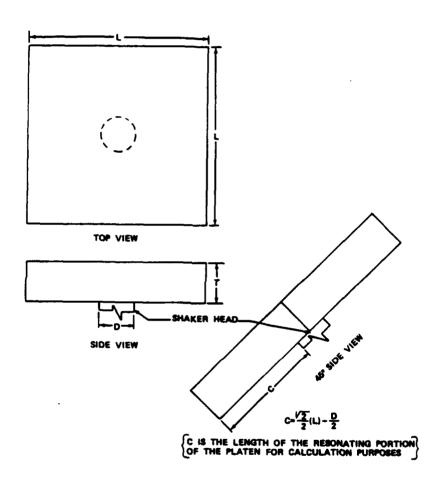

Figure 2. Illustration of Typical Flat Plate Platen Attached to Cylindrical Shaker Head

#### where

- $f_N = Natural frequency in Hertz$
- E = Young's Modulus of Elasticity of Platen Material, 1b/sq in.
- Angle of the slope of the pyramid measured from the base along the edge formed by any two sides that come together up to the apex in degrees (Figure 1).
- W = Weight of the corner-most test specimen, fixture/adapters, and bolt heads in pounds.
- A = Platen area displaced by the corner-most test specimen and its fixturing in square inches.
- ρ = Density of platen material in lb/cu in.
- C = Distance from platen corner to shaker head in inches.

This equation will determine the natural frequency of a platen corner for various angles  $\phi$ . (Test fixture engineers should already have determined all other inputs to the equation.) However, several very practical considerations are not taken into account by following this equation:

- The edges around the perimeter of the platen form a wedge. There will probably be insufficient material to bolt the test specimens and their respective fixtures/adaptors to the platen.
- As was discussed previously, the shaker head may not be of sufficient thickness to provide a significant enough increase in moment of inertia. If it is not, the platen will have to compensate by having its truncated portion take on a geometric shape that allows bolting onto the shaker head.
- The angle  $\phi$  was convenient for formula derivation, but should not be used on fabrication drawings. The slope will have to be restated in terms of the angle formed by any one of the pyramid's sides with respect to the base. This conversion is simply:

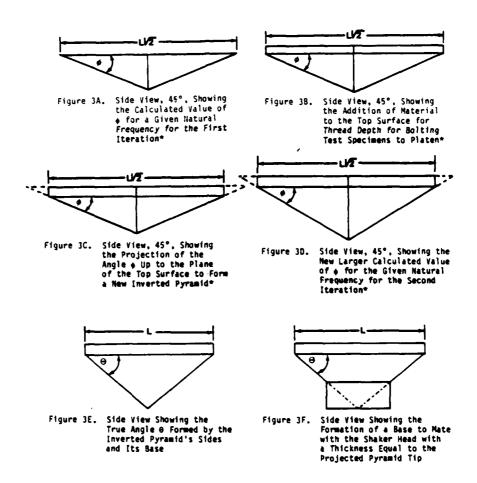

$$\theta = ARCTAN \left(\sqrt{2} \tan \phi\right) \tag{2}$$

The problem of the corners of the platen forming a wedge that is too thin can be solved by adding a mass of constant thickness to the top of the platen. This was not taken into account during the original derivation, because there is a transition of the neutral axis from the top constant thickness portion of the platen to the variable thickness portion when the line of bending moves from the corner towards the shaker head. The differential equation becomes extremely unwieldy, and the final equation would be several magnitudes larger than Equation (1). It was decided that a short iteration process would perfom the job faster and easier, be almost as accurate (any errors would be on

the conservative side, i.e., a natural frequency slightly higher than the calculations indicate), yet much lighter than a platen of constant cross section. The computer program in Appendix B performs all of the calculations necessary to design the platen. The program performs in the following order.

- a. It steps through increasingly larger angles of  $\phi$  using Equation (1) until the natural frequency is equal to, or just exceeds, the maximum frequency required by the test plan (Figure 3A).
- b. The program then adds a constant thickness mass to the top of the platen to ensure sufficient thread depth for mounting test specimens. This will lower the natural frequency below that desired because of the added mass (Figure 3B).
- c. Next, the program calculates a new value for the distance from the corner of the platen to the shaker head by projecting the angle  $\phi$  to form a new wedge with the added mass (Figure 3C). This will drop the natural frequency again.
- d. Using Equation (1) again, the program steps through increasingly greater values of  $\phi$  until the natural frequency is equal to or slightly greater than that of the test plan (Figure 3D).
- e. The program now moves the distance from the corner of the platen back to where it was (paragraph b above) with the top constant thickness mass, but with the value of  $\phi$  as newly calculated in paragraph d. This will raise the natural frequency slightly above that required by the test plan.
- f. The program now computes a new angle,  $\theta$  for fabrication. It is the angle the sides of the pyramid make with the base (Figure 3E).
- g. The minimum thickness of the mating surface of the platen to the shaker head is calculated by projecting the angle  $\theta$  to the center of the platen. The distance from the platen's top surface to this projected point is the recommended thickness of the platen at the mating surface (Figure 3F). This will assure that the line of bending will occur where the calculations assume it will, at the point where the platen's diagonal intersects the shaker head.
- h. Finally, it calculates the estimated platen weight. If the platen weight, when added to the specimen and fixture weight, exceeds that which the shaker armature can support for the maximum displacement required, then either a new layout with less test specimens should be considered or a platen material of high damping should be chosen. If the latter route is taken, the calculations should be rerun with a lower natural frequency until an acceptable weight is reached.

If the computer program is used for the above set of calculations, the display on the computer screen will show the side and bottom views of the platen with all critical dimensions. At the bottom of the screen is a window showing all of the critical dimensions required to fabricate the item, with the exception of the specimen mounting holes. These should have been determined in advance before the computer program was run.

\*NOTE: Refer to Figure 1 for a detailed illustration and explanation of the 45° side view.

#### 4. SPECIMEN DAMPING CAPACITY

### Background.

Damping is the term given for the conversion of strain energy to heat energy when the strain energy results from the kinetic energy bending the mechanical system. Damping results from the intermolecular friction that is experienced when there is alternating compression/tension strain from vibration. Without damping, every mechanical device that is excited at its resonant frequency would fail from metal fatigue. This is because the spring force is equal in magnitude and in the opposite direction from the mass force, thereby putting the two forces in dynamic equilibrium. The only structural force available to oppose the vibrating input forces (which are neither a spring force or a mass force, but are external to the mechanical system) would be the damping force, which is the product of a damping constant multiplied by the sinusoidal velocity of the vibration input.<sup>4</sup>.

Although the actual damping constant, or the damping force, may possibly be of interest in specific applications, the specific damping capacity (SDC) is of greater interest to the designer of test fixtures. When it is not possible to design a platen that will not experience resonance somewhere within the vibration spectrum of the test plan, it becomes necessary to select a material that has a reasonable amount of damping and yet not compromise other important qualities such as density, modulus of elasticity, or machinability. Therefore, when selecting material, there is a compromise among relative damping, relative density, the modulus of elasticity/density ratio, and relative machinability.

#### 5. SPECIFIC DAMPING CAPACITY

The specific damping capacity (SDC) has units of percent per cycle (%/cyc). The value of the SDC increases as the vibration-induced stress in the material increases. Therefore, anytime an SDC number is quoted, a stress level is quoted also. Since the sole objective of a vibration platen is to simply hold bolted test specimens while in a vibration environment, you can reasonably expect the lowest stress level values of the SDC to be acceptable.

Close examination of Figure 4 shows that a <u>rough estimate</u> of the impact of the SDC on the vibration amplitude can be calculated by using an <u>inverse proportion</u>. An example of this would be Equation 3:

$$x_1 (SDC_1) = x_2 (SDC_2)$$
 (3)

where

- X<sub>1</sub> = The relative amplitude at resonance of a platen mode of material #1
- $X_2$  = The relative amplitude at resonance of a platen made of material #2
- $SDC_1$  = Specific damping capacity of material #1
- $SDC_2$  = Specific damping capacity of material #2

REFRENCE: Stephen C. Eristsen, Magnesium's High Damping Capacity for Automotive Naise and Vibration Attenuation, May, 1975. By Parminian.

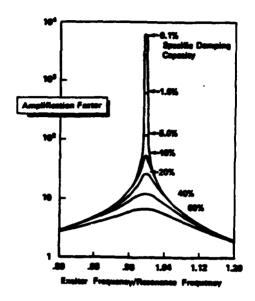

Figure 4. Influence of Specific Damping Capacity on Theoretical Resonance Amplification Factor

If you were to pick a reference material from a past test run with a logged vibrational amplitude at resonance, you could easily substitute the SDC of any other material to determine its probable vibrational amplitude. However, a ratio of  $X_2$  to  $X_1$ , where  $X_1$  would be the reference material, would suffice just as well.

#### 6. MAGNESIUM AS A PLATEN MATERIAL

#### Background.

When the test program requires vibration frequencies higher than test economics or physical constraints will permit a resonance-free platen design, then the selection of fabrication material with a high SDC becomes important. Two structural materials that offer SDC's sufficiently high for a designer's consideration are usually considered, iron and magnesium. Equation (1) illustrates the importance of a high elastic modulus to density ratio in any material selection. The higher this ratio, the higher the resonant frequency. Also, since the total weight suspended on the armature of the electrodynamic shaker greatly affects the system's displacement (this is most important at very low frequencies), platen density becomes critical. In other words, the lighter the material, the higher the displacement of oscillation.

Table 1 compares the densities and the elastic moduli to density ratios of two classes of cast iron to that of cast magnesium. Iron is about four times more dense than magnesium, and the elastic modulus to density ratio can be as low as less than half that of magnesium. Both of these qualities make cast iron ideal for stationary machinery or vehicles where traction and vibration damping are important considerations. However, a platen for vibration testing requires the opposite qualities, and magnesium is the wiser choice.

#### 7. WHICH MAGNESIUM ALLOY SHOULD BE USED?

The fixture designer can choose the magnesium for a platen from the alloys available, the fabrication method (such as sand cast or wrought), and heat treat methods. Extensive research into the effects of these metallurgical factors in relation to the SDC has provided these significant findings:

- The SDC has an inverse relationship to alloy content; i.e., the lower the alloy content, the higher the SDC.
- Cast magnesium, which provides no grain orientation, has the highest SDC of any fabrication method. Any working of the magnesium will have adverse effects on its use as a good vibration damping material.
- Heat treating to increase the tensile yield strength will lower the SDC.<sup>5</sup>

Figure 5 illustrates the alloying effect on the SDC of magnesium and other structural materials. It also shows how changing the bending stress levels changes the SDC. Particularly notice:

- How poor a material aluminum is. Because of its cost and availability, aluminum has long been used as a platen material, thereby overstressing test components greatly at resonance.
- How high the SDC is for both unalloyed magnesium and KIA magnesium, but the latter is able to withstand much higher stress levels.<sup>4</sup>

Figure 6 shows oscilloscope traces of several sand-cast magnesium and aluminum alloys that have been allowed to decay in their vibration levels after receiving the same initial excitation. Magnesium K1A has a dramatic effect when compared with the other materials.  $^5$ 

#### The K1A Magnesium Alloy

and Leveries arriveral bosossis, assesses, arrivera preseder accepte accepted

As may be suspected, K1A is a magnesium with only one alloy. Its chemical composition is shown in Table 2. The very low amount of the single alloy, zirconium, is sufficient to bring the yield tensile stress up from a little over 1,000 psi for unalloyed magnesium to a minimum of 6,000 psi for the K1A-type of magnesium (Table 3). This yield stress level can be expected to more than adequately handle any anticipated stress from a vibration test. If, however, there is any reason to suspect the bending stress level in the platen, a simple stress calculation at the highest programmed "g" loading can be performed. If the stresses approach or exceed 5,000 psi, the computer program found in Appendix B should be rerun with a greater tread depth of the top portion of the platen.

#### APPENDIX A

# A DERIVATION OF THE NATURAL FREQUENCY EQUATION FOR VARIABLE THICKNESS PLATENS

#### 1. INTRODUCTION

When it resonates, each corner of a shaker's inverted, truncated pyramid behaves as a cantilevered, variable thickness, right triangular plate as illustrated in Figure 1 of the text. If loading is equal on all four corners of the test specimen, they will resonate at the same frequency. If the loading is unequal, the corners will not only resonate at different frequencies, but the cantilevered line from which the bending originates may shift as well. Therefore, any generalized equation must be in terms of (a) the distance from the corner of the platen to the line where bending begins; (b) equivalent mass loading; (c) area moment of inertia and; (d) Young's modulus of elasticity.

#### 2. RALEIGH METHOD OF NATURAL FREQUENCY CALCULATION

The Raleigh method of natural\* frequency calculation has been found to produce values that agree closely with experimental findings if accurate assumptions are made of the physical characteristics of the vibrating system. The equation for this method is:

$$\omega = \sqrt{g} \frac{f Y dx}{f Y^2 dx}$$
 (A-1)

where

- $\omega$  = Natural frequency, radians/sec
- Y = Equation for the deflection of the vibrating system, inches
- g \* Acceleration due to gravity, which is a constant of 386.4 in./sec<sup>2</sup>

The deflection is found by solving the fourth-order differential equation:\*\*

$$\frac{d^4Y}{dX^4} = \frac{W_T}{EI} \tag{A-2}$$

<sup>\*</sup>Hansen, H.M., and Citenea, Paul F. Mechanics of Vibration, John Wiley and Sons, New York, NY. 1952.

<sup>\*\*</sup>Popov, E.P. Mechanics of Materials, Printice-Hall, Inc., New York, NY. 1952.

where:

WT = total loading on the vibrating system, lb/in.

E = Young's Modulus of Elasticity, 1b/in.<sup>2</sup>

I = Area moment of inertia, in.

The primary problem in solving Equation A-2 is determining the generalized expressions of  $W_T$  and I for a specimen loaded, inverted truncated pyramid, right triangular, cantilevered plate. The moment of inertia will be calculated first.

## Equations for Moment of Inertia and Axis of Bending

Following is the equation for the moment of inertia of a right-triangular plate with an isosceles triangular cross section where the two angles angles are and the thickness changes "x tan" as shown in Figures A-1A and A-1B.

## a. Moment of Inertia.

$$I = \frac{(\text{width})(\text{thickness})^3}{36}$$

where:

ed possobna provincial besoners consiste sorrors consistent essential

Width = 
$$2x$$

Thickness = x tan o

$$I = \frac{(2x)(x \tan \phi)^3}{36}$$

$$I = \frac{x^4 \tan^3 \phi}{18} \tag{A-3}$$

To simplify for future calculation

Let D = 
$$\frac{\tan^3 \phi}{18}$$
 (A-4)

then 
$$I = Dx^4$$
 (A-5)

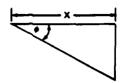

Figure A-1A. Geometry of the Triangle Formed by the Intersection of Two Planes of a Pyramid

The distance X is measured from the inverted pyramid's corner towards its center. The angle  $\phi$  is measured from the base to the line of intersection.

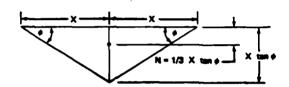

Figure A-18. Geometry of the Cross-Section of the Inverted Pyramid at Distance X from the Corner and Perpendicular to Figure A-18

b. <u>Neutral Axis of Bending</u>. The centroid is located halfway between the left and right edges of the platen (along the diagonal) and one-third of the way down from the top surface; therefore,

$$N = (1/3) \times \tan \phi \tag{A-6}$$

## Calculation of Load

a. <u>Platen Load</u>. The cross-sectional area varies as the distance "x" from the corner increases. The change in cross-sectional area is one-half the function of both the width and thickness:

d area = 1/2 (d width) x (d thickness)
$$\iint da \text{ area = } 1/2 \iint (2dx)(\tan \phi dx)$$

$$\iint da \text{ area = } \tan \phi \iint dx2$$

At x = 0, all constants of integration = 0

then 
$$a = 1/2 \times 2 \tan \phi$$
 (A-7)

This, then is the cross-sectional area at any distance "x" from the platen corner. To get the distributed platen load, simply multiply the area by the density  $\rho$  and obtain:

$$Wp = 1/2 \rho \times 2 tan \phi \qquad (A-8)$$

b. Specimen Load. The natural frequency of a cantilever is most affected by masses that are furthest from the edge of bending. The greater the mass and the further it is from this edge, the lower the natural frequency. This is because the natural frequency is related to the deflection; therefore, to simplify the deflection equation, one can assume that the weight per displaced unit area of the corner-most test item is the same for the entire triangular plate being considered. (Test prudence would dictate, wherever possible, that the lightest items per square inch go at the extreme corners of the platen to get the highest natural frequency). Include the weight of the test item, the adapters (if any), and the bolt heads to obtain the most accurate estimate of the cantilever's loading. This total specimen weight shall be designated as "Wy." Next, calculate the area displaced on the platen by the test specimen and all associated hardware and designate this area as "A." This provides a load pressure of W/A in pounds per square inch for the corner-most position on the test platen. What is now needed is the equivalent distributed load as the right triangular area expands from the corner to the line of bending. This load increases at a rate of "2x" since the width expands at twice the rate as the diagonal distance from the platen corner increases. The specimen load becomes:

$$Wp = 2 \frac{W}{A} \times (A-9)$$

c. Total Platen Load. The total platen load is the addition of the specimen load, Equation A-9, to the platen load, Equation A-8. It now becomes:

$$W_T = W_X + W_D$$

$$W_T = 2 \frac{W}{A} \times + 1/2 \rho \times^2 \tan \phi$$
 (A-10)

To simplify for future number manipulation:

$$let B = 2 \frac{W}{A}$$
 (A-11)

and 
$$G = 1/2 \rho \tan \phi$$
 (A-12)

then 
$$W_t = Bx + Gx^2$$
 (A-13)

With both the load and moment of inertia equations developed, the deflection can now be derived.

## Calculation of Deflection

From Equation A-2 we get the equation for deflection:

$$\frac{d^4y}{dx^4} = \frac{WT}{FI}$$

The solution to this fourth order differential equation, fortunately, is four easy steps of integration:

$$S = \int W_T dx + S_0 \qquad (A-14)$$

$$M = \int Sdx + M_0 \qquad (A-15)$$

$$\Psi = \int \frac{M}{EI} dx + \Psi_0 \qquad (A-16)$$

$$Y = \int \Psi dx + Y_0 \qquad (A-17)$$

where:

S = shear load, 1b

M = moment load, in.-lb

 $\Psi$  = slope, rad

Y = deflection, in.

The mathematical work will follow these steps with integration starting from the free end and going to the fixed end, as shown in Figure A-1.

Shear Calculation

From Equation A-14

$$S = \int W_T dx + S_0$$

From Equation A-13

$$W_T = Bx + Gx^2$$

then

$$S = \int (Bx - Gx^{2})dx + S_{0}$$

$$S = 1/2 Bx^{2} + (1/3)Gx^{3} + S_{0}$$
at  $X = 0$ ,  $S_{0} = 0$ 

therefore

$$S = 1/2Bx^2 + (1/3)Gx^3$$
 (A-18)

Moment Calculation

From Equation A-15

$$M = \int Sdx = M_0$$

Substitute the value of S from Equation A-18, into the above equation:

$$M = \int (1/2Bx^2 + (1/3)GX^3)dx + M_0$$

$$M = (1/6)Bx^3 + (1/12)GX^4 + M_0$$
at X = 0, M<sub>0</sub> = 0

Therefore:

$$M = (1/6)Bx^3 + (1/12)Gx^4$$
 (A-19)

## Slope Calculation

From Equation A-16

$$\Psi = \int \frac{M}{EI} dx + \Psi_0$$

From substituting Equations A-5 and A-19 into Equation A-16, we get:

$$\Psi = \int \frac{1/6Bx^3 + 1/12Gx^4}{ED x^4} dx + \Psi_0$$

$$\Psi = \frac{B}{6 ED} \ln x + \frac{G}{12 ED} x + \Psi_0$$

At X = C (see Figures 2 and 3),  $\Psi = 0$ 

Then

$$\Psi_{0} = -\left(\frac{B}{6 \text{ ED}} \ln C + \frac{GC}{12 \text{ ED}}\right)$$

$$\Psi = \frac{B}{6 \text{ ED}} \ln x + \frac{G}{12 \text{ ED}} x - \left(\frac{B}{6 \text{ ED}} \ln C + \frac{GC}{12 \text{ ED}}\right) \tag{A-20}$$

Deflection Calculation

From Equation A-17:

$$Y = \Psi dx + Y_0$$

Substitute in the value from Equation A-20 and we get

$$Y = \int \left( \frac{B}{6ED} \ln x + \frac{G}{12ED} x - \frac{B}{6ED} \ln C - \frac{GC}{12ED} \right) dx + Y_0$$

$$Y = \frac{xB}{6ED} \ln x - \frac{B}{6ED} x + \frac{G}{24ED} x^2 - \frac{B \ln C}{6ED} x - \frac{GC}{12ED} x + Y_0$$

At x = C, Y = 0

then

$$Y_0 = -\frac{CB}{6ED} \ln C + \frac{BC}{6ED} - \frac{GC^2}{24ED} + \frac{BC}{6ED} \ln C + \frac{GC^2}{12ED}$$

$$Y_0 = \frac{BC}{6ED} + \frac{GC^2}{24ED}$$

$$Y_0 = \frac{BC}{6ED} \ln x - \frac{B}{6ED} x + \frac{G}{24ED} x^2 - \frac{B \ln C}{6ED} x - \frac{GC}{12ED} x + \frac{BC}{6ED} + \frac{GC^2}{24ED}$$

$$Y = \frac{1}{24ED} \left( 4 \times 8 \ln x - 48x + Gx^2 - 48x \ln c - 2G Cx + 48c + Gc^2 \right) \quad (A-21)$$

This completes the derivation of the deflection equation for a right triangular plate with an isosceles triangular cross section.

#### Calculation of Natural Frequency

Equation A-1 provides the Raleigh equation for determining the natural frequency of a vibrating system. It is:

$$\omega = \sqrt{Q \frac{f Y dx}{f Y^2 dx}}$$

This requires an additional integration step of the numerator and an additional integration step after squaring in the denominator. To prevent confusion in the calculations, let's set:

$$k = \int Y dx \qquad (A-22)$$

and

$$j = f Y^2 dx (A-23)$$

First, let's solve for "k" by substituting Equation A-21 into Equation A-22:

$$k = \frac{1}{24ED} \int_{0}^{c} (4 \text{ Bx ln x} - 48x + Gx^{2} - 48x ln C-2GCx + 48C + GC^{2}) dx$$

$$k = \frac{1}{24ED} \left[ \int_{0}^{c} \left( x^{2} \left( \frac{\ln x}{1+1} - \frac{1}{(1+1)^{2}} \right) \right) - 2Bx^{2} + \frac{1}{3Gx^{3}} - 2Bx^{2} \ln C \right]$$
$$- GC_{x}^{2} + 4BCx + GC^{2}x$$

$$k = \frac{1}{24ED} \left[ \begin{array}{c} c \\ 2Bx^2 \ln x - 2Bx^2 + 1/3Gx^3 - 2Bx^2 \ln c - Gcx^2 + 4Bcx + Gc^2x \end{array} \right]$$

$$k = \frac{1}{24ED} \left( 2BC^2 \ln C - 3BC^3 + 1/3GC^3 - 2BC^2 \ln C - GC^3 + 4BC^2 + GC^3 \right)$$

$$k = \frac{1}{24ED} \left( 1/3GC^3 + BC^2 \right)$$

$$K = \frac{C^2}{24ED} \left( 1/3 \text{ GC} + B \right) \tag{A-24}$$

Now, solve for "j" by substituting Equation A-21 into A-23:

$$j = \left(\frac{1}{24ED}\right)^2 \int \left(4 \times 8 \ln x - 48x + Gx^2 - 48x \ln C - 2GCx + 4BC + GC^2\right)^2 dx$$

$$j = \left(\frac{1}{24ED}\right)^2 \int \left(16 B^2 x^2 (\ln x)^2 - 32B^2 x^2 \ln x + 8BG x^3 \ln x - 32B^2 x^2 \ln C\right)$$

$$lnx - 16BCGx^2 ln x + 328^2 C x ln x + 8BC^2Gx ln x + 16B^2x^2 - 8BGx^3$$

$$+ 328^2x^2 \ln C + 248CGx^2 - 328^2Cx - 248C^2Gx + G^2x^4 - 88Gx^3 \ln C$$

$$-4CG^2x^3 + 6C^2G^2x^2 + 16B^2x^2(1n C)^2 + 16BCGx^2 1n C - 32B^2Cx 1n C$$

$$-8BC^2Gx^1n C - 4G^2C^3x + 16B^2C^2 + 8BC^3G + G^2C^4)dx$$

$$j = \left(\frac{1}{24ED}\right)^2 \left[\frac{56}{27} B^2 C^3 + \frac{23}{18} BC^4 G + \frac{1}{5} C^5 G^2\right]$$

$$j = \left(\frac{1}{24ED}\right)^2 C^3 \left(\frac{56}{27} B^2 + \frac{23}{18} BC G + \frac{1}{5} C^2 G^2\right) \tag{A-25}$$

By substituting Equation A-24 into A-22 and A-25 into A-23 and both of these into Equation A-1, we get:

$$\omega = \sqrt{\frac{\left(\frac{1}{24ED}\right)^2 c^2 \left(\frac{1}{3} c_{G} + B\right)}{\left(\frac{1}{24ED}\right)^2 c^3 \left(\frac{1}{5} c_{G}^2 + \frac{23}{18} B_{G}^2 + \frac{56}{27} B^2\right)}}$$

$$\omega = \sqrt{\frac{\frac{24EDg}{c}}{c}} \frac{\frac{1}{3} c_{G} + B}{\frac{1}{5} c_{G}^2 + \frac{23}{18} B_{G}^2 + \frac{56}{27} B^2}$$

The natural frequency is usually expressed as:

$$f_N = \frac{1}{2\pi} \omega$$

Simplifying, we get:

$$f_{N} = 15.3265 \sqrt{\frac{ED}{C}} \left( \frac{\frac{1}{3} CG + B}{\frac{1}{5} C^{2}G^{2} + \frac{23}{18} BCG + \frac{56}{27} B^{2}} \right) (A-26)$$

Substituting Equations A-4, A-11, and A-12 into Equation A-26, we get:

$$f_{N} = 3.61249$$

$$C$$

$$\frac{1}{1080} = \frac{1}{54 \cdot C^{2} \rho^{2} + 1380 \cdot C - \rho \cdot \tan \phi + 8460 \cdot \frac{W^{2}}{A^{2}}}$$

$$f_{N} = 48.47$$

$$\frac{E \tan^{3} \phi}{C}$$

$$\frac{E \tan^{3} \phi}{C}$$

$$\frac{C \rho \tan \phi + 12 - A}{A}$$

$$\frac{W}{A}$$

$$\frac{W}{A}$$

$$\frac{W^{2}}{A}$$

$$\frac{W^{2}}{A}$$

$$\frac{W^{2}}{A}$$

$$\frac{W^{2}}{A}$$

$$\frac{W^{2}}{A}$$

This, then, is the final equation for determining the natural frequency of a corner of a truncated inverted pyramid. This equation is found in the main text of this report as Equation 1.

## APPENDIX B

## COMPUTER PROGRAM FOR DETERMINATION OF OPTIMUM DESIGN PARAMETERS

This program determines the optimum design parameters for an inverted truncated pyramid type of platen for holding test specimens during vibration testing.

L.J. LIPP

USAAMCCOM Product Assurance Directorate For Chemical Systems 1985

THE PROGRAM REQUIRES THAT THE FIXTURE DESIGNER COMPLETE A LAYOUT OF THE TOP OF A SQUARE VIBRATION PLATEN BEFORE GETTING ON THE COMPUTER. THE DESIGNER IS EXPECTED TO HAVE:

- 1. ARRANGED ALL OF THE TEST SPECIMENS SO THAT THOSE WITH THE LEAST WEIGHT (INCLUDING FIXTURE ADAPTERS AND BOLTS) PER DISPLACED PLATEN AREA ARE AT THE FOUR CORNERS;
- 2. THE TEST SPECIMENS AS CLOSE TOGETHER AS POSSIBLE, YET WITH ROOM FOR WRENCHES, POWER AND SIGNAL CABLES, ETC. TO KEEP THE PLATEN'S SQUARE DIMENSIONS AS SHORT AS POSSIBLE;
- 3. SELECTED THE PLATEN MATERIAL AND TO KNOW ITS YOUNG'S MODULUS OF ELASTICITY AND DENSITY;
- 4. DETERMINED THE MINIMUM DEPTH REQUIRED FOR THE BOLT THREADS TO FASTEN THE TEST SPECIMENS AND FIXTURES DOWN TO THE PLATEN.

HAVE YOU COMPLETED THESE PRELIMINARY DESIGN DETAILS? <Y OR N> IMPORTANT NOTE: ALL RESPONSES TO THE FOLLOWING QUESTIONS ARE TO BE IN DECIMAL FORM, NOT FRACTIONS.

WHAT IS THE LENGTH OF A SIDE OF YOUR SQUARE PLATEN IN INCHES?

WHAT IS THE DIAMETER OF THE SHAKER HEAD IN INCHES?

WHAT IS THE MINIMUM MATERIAL THICKNESS REQUIRED TO BE TAPPED TO BOLT THE TEST SPECIMENS TO THE PLATEN IN INCHES?

WHAT IS THE MAXIMUM FREQUENCY REQUIRED IN THE TEST PROGRAM IN HERTZ?

WHAT MATERIAL HAVE YOU CHOSEN FOR THE PLATEN? ?MAGNESIUM KIA

WHAT IS MAGNESIUM KIA'S YOUNG'S MODULUS OF ELASTICITY IN POUNDS PER SQUARE INCH? ?7000000

WHAT IS MAGNESIUM KIA'S DENSITY IN POUNDS PER CUBIC INCH? 10.07

ASSIGN EACH CORNER OF THE PLATEN A NUMBER SO THE WEIGHTS OF THE AREAS DISPLACED BY THE TEST SPECIMENS AND THEIR FIXTURING CAN BE IDENTIFIED BY THEIR LOCATION ASSIGNMENT.

WHAT IS THE WEIGHT OF THE TEST SPECIMEN, FIXTURING, BOLTS, WASHERS, ETC. IN CORNER 1? ?11

WHAT IS THE AREA DISPLACED ON THE PLATEN BY THE TEST SPECIMEN, FIXTUR-ING, ETC. IN CORNER 1?

THE CORNER'S LOAD IS 1 PSI

WHAT IS THE WEIGHT OF THE TEST SPECIMEN, FIXTURING, BOLTS, WASHERS, ETC. IN CORNER 2? ?11

WHAT IS THE AREA DISPLACED ON THE PLATEN BY THE TEST SPECIMEN, FIXTUR-ING, ETC. IN CORNER 2?

THE CORNER'S LOAD IS 1 PSI

WHAT IS THE WEIGHT OF THE TEST SPECIMEN, FIXTURING, BOLTS, WASHERS, ETC. IN CORNER 3? ?11

WHAT IS THE AREA DISPLACED ON THE PLATEN BY THE TEST SPECIMEN, FIXTUR-ING, ETC. IN CORNER 3?

THE CORNER'S LOAD IS 1 PSI

WHAT IS THE WEIGHT OF THE TEST SPECIMEN, FIXTURING, BOLTS, WASHERS, ETC. IN CORNER 4? ?11

WHAT IS THE AREA DISPLACED ON THE PLATEN BY THE TEST SPECIMEN, FIXTUR-ING, ETC. IN CORNER 4?

THE CORNER'S LOAD IS 1 PSI CORNER NUMBER 1 HAS THE GREATEST LOAD OF 1 POUNDS PER SQUARE INCH.
